

Run outcomes: event vs full-path recalculation, by planner

Recalculating whenever any later segment is blocked (full-path) costs 1.1-2.0x the replans at 20 ms and changes finishes by Voronoi -1, PRM -13, Visibility Graph -25, with clean finishes -1, -7, -8: more work, no safety gain. Event rebuilds when the segment to the next waypoint is blocked; full-path also rebuilds when any later segment is blocked, the rule Costa and Tonidandel (2024) describe for SSL planners without a separate avoidance layer. Same scenarios for both.
