

Route lifetime: event vs cycle for three planners

Event (ours) keeps a route $1.6\text{--}4.7\times$ longer than cycle at the same check interval. Bars: event; $\diamond$ markers: cycle on the same 200 scenarios. Lifetime = average time a route is followed before a new one replaces it. Every policy first tests the straight line to the target and keeps driving straight while it is clear, so only a detour (or a step out of an obstacle zone) replaces a route; cycle routes therefore outlast one check.
